5

6 **RELATED U.S. APPLICATION DATA:**

7 This application claims the benefit of and is a continuation in part of United States
8 Provisional Application Serial No. 60/108,364, filed November 13, 1999, for A NOVEL
9 METHOD FOR PRODUCTION OF MIXED ALCOHOLS FROM SYNTHESIS GAS.
10

11 **BACKGROUND OF THE INVENTION**

12 **FIELD OF THE INVENTION**

13 The present invention relates to a novel slurry-phase method to produce mixed alcohols
14 from synthesis gas by utilizing a nanosized catalyst. The catalyst is activated by nanosizing and
15 sulfiding during catalyst preparation.

OFFICE OF PETITIONS

16
17 **DISCUSSION OF THE PRIOR ART**

18 Synthesis gas, hereinafter "syngas" is produced from any organic/carbonaceous source,
19 such as, but not limited to municipal solid waste (MSW), refuse derived fuel (RDF), biogas from a
20 digester, sewage sludge, chicken manure, turkey manure, other animal and agricultural waste,
21 corn stover, switch grass, timber, grass clippings, construction demolition materials, cotton gin
22 waste, biomass, landfill gas, natural gas and the like. The catalytic production of mixed alcohols
23 from synthesis gas is a well established route and the literature contains numerous examples
24 pertaining to this transformation. Of particular interest is a method described in U.S. patents No.
25 4,675,344; 4,749,724; 4,752,622; 4,752,623; and 4,762,858, all originally assigned to Dow
26 Chemical Company. These patents describe, in general, a micron-size supported catalyst based on
27 molybdenum disulfide (MoS₂). Mixed alcohols, primarily C₁- C₄, i.e. methanol – butanol, are

1 produced in good yields when the Dow catalyst is used in a packed column or fluidized bed. The
2 best yield of oxygenates fraction is approximately 20%, on a CO₂-free basis, with up to 85%
3 selectivity to mixed alcohols. The rate of 0.1-0.4 grams product/gram catalyst/hour is claimed by
4 the use of the Dow catalysts at 240-325°C reaction temperature and 700-3000 psig. The above
5 Dow patents and the references discussed and cited therein are incorporated by reference in this
6 application.

7 Review of the above noted prior art and references will show that a process and catalyst
8 that improves upon conditions of high temperature and high pressure conversion of synthesis gas
9 to mixed alcohols, and which provides a higher conversion rate of synthesis gas to mixed alcohols
10 per pass over/through the catalyst are highly desirable, especially for commercial applications.

11 For commercial application, a process that improves upon conditions of high temperature
12 and high pressure and allows higher conversion per pass are highly desirable. To make a
13 commercially significant alcohol process the catalyst must be highly efficient as well as the
14 conditions in which the catalyst operates. The efficient catalyst must yield a high ratio of mass of
15 product per given mass of catalyst in a given period of time. The catalyst must be stable and
16 active over long periods of time before regeneration or replacement of the catalyst is required.
17 When the feed gas has a low ratio, ideally when the H₂/CO ratio is less than 2 to 1, the catalyst
18 will be highly selective to produce a commercial product to avoid purification or removal and
19 disposal of by-products with the addition of a distillation tower that will split the product into two
20 or more product streams.

21 When the mixture is used as a neat fuel for automobiles the presence of C₁ alcohol, i.e.
22 methyl alcohol, is more beneficial than when the alcohols are used as a commercial blend in

1 gasoline. As used in this application, the weight ratio of methanol or C₁ alcohol to C₂ + alcohols
2 means the higher alcohols, such as ethanol, propanols, butanols, etc., taken as a whole for
3 calculation purposes. This number may be calculated by determining the weight fraction of
4 methanol in the mixed alcohols. The esters or ethers portion of the alcohol mix are not included
5 in either the C₁ to C₂+ numbers. It is therefore understood that it would be beneficial to prepare
6 mixed alcohols, primarily C₁ – C₄, from synthesis gas derived from any carbonaceous source. It
7 would also be beneficial to produce mixed alcohols in a highly efficiently manner by a catalytic
8 method, i.e. in high yield per pass to avoid gas recycle under mild conditions of temperature and
9 pressure.

11 SUMMARY OF THE INVENTION

12 It is therefore an object of the present invention to prepare mixed C₁ – C₄, alcohols,
13 primarily from synthesis gas derived from any carbonaceous source.

14 It is therefore an object of the present invention to produce mixed alcohols in a highly
15 efficient manner by a catalytic method, having a high yield per pass to avoid gas recycle under
16 mild conditions of temperature and pressure.

17 The present invention provides a novel method for producing mixed alcohols by
18 combining one or more of the following steps. First a catalyst is selected from the Group VI
19 metals, namely Cr, MO, W and mixtures thereof. Next, the selected metal is nanosized to a mean
20 particle diameter (MPD) of less than about 100 nm. Nanosizing the metal is an especially
21 important feature of the present invention, in that nonosizing provides more surface area per unit

1 volume of the metal, thereby enhancing the reaction rates. The nanosized metal catalyst is then
2 sulfided to enhance its resistance to the catalyst poisons that are normally present in syngas.

3 Nanosizing of the metal catalyst can be achieved by a variety of methods. One preferred
4 method of nanosizing is sonication of a carbonyl precursor of the metal. An example of
5 nanosizing is found in the literature reference (Mdleleni et al. J. Amer. Chem. Soc. 120 6189-6190
6 (1998)). Catalyst-sulfiding can be achieved during or after the nanosizing procedure.

7 During the alcohol production from syngas production, the nanosized, sulfided Group VI
8 metal catalyst may be unsupported, or it may be supported on a high surface area support such as
9 carbon, alumina, silica or the like. In either arrangement the nanosized catalyst is suspended in an
10 inert solvent, such as a high molecular weight hydrocarbon solvent such as ethylflo-164, to form
11 a slurry. Suspension of the nanosized catalyst allows excellent heat management during the
12 thermal operations, and this in turn increases mixed alcohol product yield.

13 The syngas is then passed through the catalyst slurry to produce alcohols in the product
14 stream. The input syngas composition varies from H_2/CO of 1/4 to 3/1 though other gaseous
15 impurities may be present. In order to enhance reaction rates, additives that make the Group VI
16 metal catalyst more susceptible to initial carbon monoxide attack are preferred. The operating
17 temperature range is from about 200°C to less than about 300°C. The operating pressure ranges
18 is from about 500 to about 3000 psig. The space-time-yield (STY) of product mixed alcohols is
19 better than those claimed by any known commercial methods, that is greater than about 0.4 gram
20 product/gram catalyst/hr. In order to enhance catalyst life, a small amount of sulfur source is
21 added either directly to the reaction vessel in which alcohols are being continuously produced, or
22 to the incoming syngas stream.

1 By combining these steps, using a novel catalyst in a novel process efficiently produces mixed
2 alcohols. In one embodiment of this invention, nanosized particles (MPD<100 nm) of
3 molybdenum are produced by the sonication method and are suspended in a hydrocarbon solvent
4 having a carbon chain length of 30. A sulfur source, being elemental sulfur itself, is added to the
5 slurry. By contacting the slurry with a stream of carbon monoxide and hydrogen in 1/2 ratio at
6 temperature in the range of about 250 to about 280°C and pressure in the range of about 500 to
7 about 200 psig pressure, mixed alcohols are produced in the product stream with STY surpassing
8 0.4 grams product/gram catalyst/hour reported with the known prior art technology.

9 These and other objects of the present invention will become apparent to those skilled in
10 the art from the following detailed description and accompanying drawings, showing the
11 contemplated novel construction, combination, and elements as herein described, and more
12 particularly defined by the appended claims, it being understood that changes in the precise
13 embodiments to the herein disclosed invention are meant to be included as coming within the
14 scope of the claims, except insofar as they may be precluded by the prior art.

15 16 **BRIEF DESCRIPTION OF THE DRAWINGS**

17 The accompanying drawing which is incorporated in and form a part of this specification
18 illustrate complete preferred embodiments of the present invention according to the best modes
19 presently devised for the practical application of the principles thereof, and in which:

20 Figure 1 is a conceptual diagram of the entire process from syngas feed to mixed alcohol
21 storage..
22

1 DETAILED DESCRIPTION OF THE PROCESS

2 During the municipal solid waste treatment process the waste material is sorted to be free of
3 all metals including aluminum, and glass. Plastics may or may not be separated depending upon
4 the value of the recycled plastics at the time. The material is then gasified, cooled and cleaned.
5 The synthesis gas that is produced by this process will be at a ratio that will vary from H_2/CO of
6 1:1.2 to 1:2 although other gaseous impurities may be present. The gaseous material will then be
7 compressed at approximately 100°F at a pressure from about 500 to about 1000 psig and passed
8 through the novel nanosized suspended Group VI metal to produce mixed alcohols with STY
9 surpassing 0.4 grams product/gram catalyst/hour.

10 The digestion of manure from all types of animals produces syngas, although manure from
11 dairies and hog farms and feedlots have been targeted. The digestion process will yield several
12 more moles of methane than of carbon dioxide. A commercially available partial oxidation unit
13 then disassociates the methane gas. The syngas from the partial oxidation unit is expected to
14 yield a 1:1 ratio of H_2 to CO . The gaseous material will then be compressed at approximately
15 100°F at a pressure from about 500 to about 1000 psig and passed through the novel nanosized
16 suspended Group VI metal to produce mixed alcohols with STY surpassing 0.4 grams
17 product/gram catalyst/hour.

18 Where waste rubber, such as tires and or autofluff become plentiful and needs to be
19 processed, a pyrolyzer will be utilized to produce syngas. The syngas ratio can vary widely with
20 these processes and the material being processed will also vary. The syngas from the pyrolyzer
21 unit is expected to yield a 1:1 or 1.1.4 ratio of H_2 to CO .

1 A steam reformer, such as those found on a typical methanol plant, may be utilized with a
2 recirculation of the hydrogen back into the process to be utilized for makeup heat as well as
3 additional carbon monoxide being manufactured from the carbon dioxide through the hydrogen
4 burner unit furnished by others in the process.

5 To provide a commercially significant alcohol process, the present invention uses a catalyst
6 and conditions which are highly efficient. To be efficient the catalyst must yield a high ratio of
7 mass product per given mass of catalyst in a given period of time. The catalyst must be stable
8 and highly active for long periods of time between regenerations. This is particularly difficult to
9 accomplish when the H_2/CO ratio of feed gas is low, such as less than about 2 to 1. Ideally the
10 catalyst is highly selective to commercial product to avoid purification or removal and disposal of
11 by-products and to avoid separation into two or more product streams. The use of a partial
12 oxidation unit before placing the syngas stream into the catalyst slurry bed, or other catalyst
13 presentation method, is chosen to make the mixed alcohol and greatly enhances the ability of the
14 catalyst to select the desired ratio of alcohols.

15 The replacement or the use of the alcohol as an additive to gasoline the ratio of the C_1 to C_2^+
16 alcohols should be no greater than a certain amount. As used in this application, the ratio of C_1 to
17 C_2^+ means the weight ratio of methanol to higher alcohols such as ethanol, propanols, butanols,
18 and the like, taken as a whole. This number may be easily calculated by determining the weight
19 fraction of methanol in the mixed alcohols with the desired mixture for mixing with gasoline to be
20 almost zero on the C_1 alcohols.

21 Through all of these processes it is desired that ethyl alcohol be a major product constituent,
22 with the yield of methanol at a very small portion of the overall product. While this process is an

1 advance over the art it would be advantageous if it were possible to increase the C₂ and other
2 alcohols and decrease the percentage of methanol in the mixes made when using the mix as a
3 blend in gasoline. Under preferred conditions, alcohols may be obtained in about 95 percent per
4 pass of the H₂/CO syngas at any preferred ratio. The selectivity of the C₂ and other higher
5 alcohols are preferred and should be obtained with this invention.

6 The space velocity of the hourly rate that the H₂/CO gas passes a given volume of catalyst in
7 an hour's time (GHSV) is a measure of the volume of the hydrogen plus carbon monoxide gas at
8 a standard temperature and pressure. The selectivity of the alcohols generally increase as the
9 space velocity increases, however conversion of the carbon monoxide decreases as the space
10 velocity increases. Some of these gases may be recycled in the reaction; however, the recycle
11 ratio of zero is within the scope of the invention because of the highly active catalyst.

12 Where shut-in natural gas, pipeline natural gas or landfill gas is plentiful it needs to be
13 processed by other means than cleaning it to enter the market place via the pipeline. The syngas
14 ratio will be fairly stable in all of these applications but should yield a very stable syngas. An
15 autotherm reformer or partial oxidation unit will be utilized to produce syngas that is expected to
16 yield a 1:1 or 1:1.2 ratio of H₂ to CO.

17 Figure 1 is a conceptual diagram of the entire process from syngas feed to mixed alcohol
18 storage. The mixed alcohol is referred to be its trademark "ECALENE".

19 It will therefore be appreciated that in the practice of the processes and in the use of the
20 catalysts of the present invention, a novel process results that efficiently produces mixed alcohols
21 from syngas.
